(Received 24 February 1994; revised 1 July 1994; accepted 22 August 1994)

Axial and tangential thickness shear vibrations of a circular cylindrical piezoelectric shell of monoclinic crystals are studied. The problems are solved analytically, and the frequency equations are derived. For a cylinder made of a rotated Y-cut quartz, the resonant frequencies are computed numerically, and it is shown that they approach that of a flat plate as the inner radius of the cylinder of finite thickness approaches infinity.

INTRODUCTION

Thickness shear vibrations of crystals and piezoelectric plates have been studied either by using the three-dimensional equations of piezoelectricity or the two-dimensional equations of the plate theory.1-3 The interest in these problems arises because of their applications as resonators. Vibrations of a circular cylindrical piezoelectric shell, with deformations assumed to be either axisymmetric or with the tangential displacement taken to be zero, and made of ceramics poled in various directions, have also been studied.4-7 In this paper, axial and tangential thickness shear vibrations of a circular cylindrical piezoelectric shell made of a monoclinic crystal are studied. We derive exact solutions of the three-dimensional quasistatic piezoelectricity equations governing the free vibrations of a cylindrical shell with traction-free and electroded inner and outer surfaces. Frequency equations are also derived and solved numerically.

I. THICKNESS SHEAR VIBRATIONS OF A PLATE

Results for the thickness shear vibrations of a monoclinic piezoelectric plate2 are summarized below for easy reference. Consider an infinite plate, shown in Fig. 1, of thickness 2h with traction-free and electroded boundaries at x2=±h. Equations governing the deformations of the plate and the relevant boundary conditions are

\[ T_{ij,j} = \rho u_{ij}, \quad -h < x_2 < h, \]
\[ D_{ij} = 0, \quad -h < x_2 < h, \]
\[ T_{2i} = 0, \quad \phi = 0 \text{ at } x_2 = \pm h, \]
where

\[ T_{ij} = C_{ijkl} S_{kl} - e_{ijkl} E_k, \]
\[ D_{ij} = e_{ijkl} S_{kl} + e_{ij} E_k, \]
\[ S_{ij} = \frac{1}{2} (u_{ij,j} + u_{ji,j}), \]
\[ E_i = -\phi_{,i}. \]

In Eqs. (1)–(7) and hereafter, T_{ij}, u_{ij}, D_{ij}, S_{ij}, and E_i are the components of the stress tensor, mechanical displacement, electric displacement, the strain tensor appropriate for infinitesimal deformations, and the electric field, respectively, \( \rho \) and \( \phi \) the mass density and the electric potential, and \( C_{ijkl}, e_{ijkl}, \) and \( e_{ij} \) the elastic, piezoelectric, and dielectric constants, respectively. Furthermore, a comma followed by an index \( j \) indicates partial differentiation with respect to \( x_j \), a superimposed dot indicates differentiation with respect to time \( t \), and a repeated index implies summation over the range of the index.

In Eqs. (1)–(7) and hereafter, T_{ij}, u_{ij}, D_{ij}, S_{ij}, and E_i are the components of the stress tensor, mechanical displacement, electric displacement, the strain tensor appropriate for infinitesimal deformations, and the electric field, respectively, \( \rho \) and \( \phi \) the mass density and the electric potential, and \( C_{ijkl}, e_{ijkl}, \) and \( e_{ij} \) the elastic, piezoelectric, and dielectric constants, respectively. Furthermore, a comma followed by an index \( j \) indicates partial differentiation with respect to \( x_j \), a superimposed dot indicates differentiation with respect to time \( t \), and a repeated index implies summation over the range of the index.

Equation (1) expresses the balance of linear momentum and Eq. (2) is the Gauss equation. The boundary conditions (3)1 and (3)2 imply that the bounding surfaces \( x_2 = \pm h \) are traction-free and have null electric potential prescribed there. Equations (4) and (5) are the constitutive relations and Eq. (6) is the strain-displacement relation; Eq. (7) is the electric-field-potential relation. Regarding \( T_{ij} = T_{ji} \) and \( S_{ij} = S_{ji} \) as vectors in a six-dimensional space with \( T_1 = T_{11}, T_2 = T_{12}, T_3 = T_{13}, T_4 = T_{23}, T_5 = T_{31}, \) and \( T_6 = T_{12} \) etc., the material constants \( C_{ijkl} \) and \( e_{ijkl} \) may be written as 6×6 and 6×3 matrices. For monoclinic crystals,

\[ e_{ij} = e_{ij}, \quad e_{12} = e_{13} = 0. \]

For the free-time-harmonic thickness shear vibrations in the \( x_1 \) direction, we seek solutions satisfying

\[ u_1 = \tilde{u}_1 (x_2) e^{i\omega t}, \quad u_2 = 0, \quad u_3 = 0, \]
\[ \phi = \tilde{\phi} (x_2) e^{i\omega t}. \]

Equations (1)–(7) become

\[ T_{21} = -\rho \omega^2 u_1, \quad D_{2,2} = 0, \quad -h < x_2 < h, \]
\[ T_{21} = 0, \quad \phi = 0 \text{ at } x_2 = \pm h, \]
\[ T_{31} = 2C_{65} S_{12} - e_{25} E_2, \quad T_{12} = 2C_{60} S_{12} - e_{26} E_2, \]
\[ D_2 = 2e_{26} S_{12} + e_{22} E_2, \quad D_3 = 2e_{36} S_{12} + e_{23} E_2, \]
\[ S_{12} = \frac{1}{2} u_{1,2}, \quad E_2 = -\phi_2. \]
wherein we have dropped the tildes superimposed upon \( u_1 \) and \( \phi \). The general solution of (10) is

\[
u_1 = a_1 \sin kx_2 + a_2 \cos kx_2, \quad (15)\]

\[
\phi = e^{26}_{22} \left( a_1 \sin kx_2 + a_2 \cos kx_2 \right) + a_3 x_2 + a_4, \quad (16)
\]

where

\[
k^2 = \rho \omega^2 / C_{66}, \quad \dot{C}_{66} = C_{66} + e^{26}_{22} / e^{26}_{22}, \quad (17)
\]

and \( a_1, a_2, a_3, \) and \( a_4 \) are arbitrary constants. Substitution from (15) and (16) into boundary conditions (11) gives the following set of homogeneous equations for the determination of \( a_1, a_2, a_3, \) and \( a_4 \):

\[
k \left( C_{66} (a_1 \cos k h - a_2 \sin k h) + e^{26}_{22} (a_1 \cos k h - a_2 \sin k h) \right) + e^{26}_{22} a_3 = 0, \quad (18)
\]

\[
k \left( C_{66} (a_1 \cos k h + a_2 \sin k h) + e^{26}_{22} (a_1 \cos k h + a_2 \sin k h) \right) + e^{26}_{22} a_3 = 0, \quad (19)
\]

\[
e^{26}_{22} (a_1 \sin k h + a_2 \cos k h) + a_3 h + a_4 = 0, \quad (20)
\]

\[
e^{26}_{22} (-a_1 \sin k h + a_2 \cos k h) - a_3 h + a_4 = 0. \quad (21)
\]

The vanishing of the determinant of the coefficient matrix of Eqs. (18)-(21) gives the following frequency equation:

\[
\sin k h (\tan k h - k h / k_{26}^2) = 0, \quad k_{26}^2 = e^{26}_{22} / \dot{C}_{66} e^{26}_{22}. \quad (22)
\]

II. AXIAL THICKNESS SHEAR VIBRATIONS OF A CIRCULAR CYLINDRICAL SHELL

We consider a cylindrical shell, shown in Fig. 2, made of a monoclinic crystal and with inner radius \( a \) and outer radius \( b \). It is more convenient to use cylindrical coordinates, and we refer the reader to Love’s book\(^8\) for the governing equations (1) and (2), constitutive relations (4), and strain-displacement relations (6) written in cylindrical coordinates. It is preferable to work in terms of physical components of stresses, strains, and the electric displacement. The constitutive relations (4) and (5), and electric-field-potential relations (7) become

\[
T_{zz} = C_{11} S_{zz} + C_{12} S_{rr} + C_{13} S_{\theta \theta} + 2C_{14} S_{\theta r} - e_{11} E_z, \quad (23a)
\]

\[
T_{rr} = C_{12} S_{zz} + C_{22} S_{rr} + C_{23} S_{\theta \theta} + 2C_{24} S_{\theta r} - e_{12} E_r, \quad (23b)
\]

\[
T_{\theta \theta} = C_{13} S_{zz} + C_{33} S_{rr} + C_{33} S_{\theta \theta} + 2C_{34} S_{\theta r} - e_{13} E_{\theta}, \quad (23c)
\]

\[
T_{\theta r} = C_{14} S_{zz} + C_{44} S_{rr} + C_{44} S_{\theta \theta} + 2C_{44} S_{\theta r} - e_{14} E_{\theta}, \quad (23d)
\]

\[
T_{zz} = 2C_{55} S_{\theta \theta} + 2C_{55} S_{rr} - e_{35} E_r - e_{35} E_{\theta}, \quad (23e)
\]

\[
T_{rr} = 2C_{55} S_{\theta \theta} + 2C_{55} S_{rr} - e_{36} E_r - e_{36} E_{\theta}, \quad (23f)
\]

\[
T_{\theta r} = 2C_{55} S_{\theta \theta} + 2C_{55} S_{rr} - e_{36} E_r - e_{36} E_{\theta}, \quad (23g)
\]

\[
D_z = e_{11} S_{zz} + e_{12} S_{rr} + e_{13} S_{\theta \theta} + e_{14} S_{\theta r} + e_{15} E_z, \quad (23h)
\]

\[
D_r = e_{22} S_{rr} + e_{22} S_{zz} + e_{22} S_{\theta \theta} + e_{22} S_{\theta r} + e_{22} E_r, \quad (23i)
\]

\[
D_{\theta} = e_{33} S_{\theta \theta} + e_{33} S_{rr} + e_{33} S_{\theta \theta} + e_{33} S_{\theta r} + e_{33} E_{\theta}, \quad (23j)
\]

For the free-time-harmonic thickness shear vibrations in the axial direction, we seek solutions of the form

\[
u_z = u_z(r)e^{i\omega t}, \quad u_r = 0, \quad u_\theta = 0, \quad \phi = \phi(r)e^{i\omega t}. \quad (24)
\]

With (24), and dropping the tildes superimposed upon \( u_z \) and \( \phi \), the governing equations and the boundary conditions simplify to

\[
\frac{\partial T_{rz}}{\partial r} + \frac{T_{rz}}{r} = -\rho \omega^2 u_z, \quad \frac{1}{r} \frac{\partial}{\partial r} (r D_z) = 0, \quad a < r < b, \quad (25)
\]

\[
S_{rz} = \frac{1}{2} \frac{\partial u_z}{\partial r}, \quad E_r = -\frac{\partial \phi}{\partial r}, \quad (26a)
\]

\[
T_{rz} = 2C_{66} S_{rz} - e_{26} E_r, \quad D_r = 2e_{26} S_{rz} + e_{26} E_r, \quad (27a)
\]

\[
T_{\theta r} = 2C_{55} S_{\theta r} - e_{25} E_r, \quad D_{\theta} = 2e_{36} S_{\theta r} + e_{25} E_r, \quad (27b)
\]

\[
T_{rz} = 0, \quad \phi = 0 \quad \text{at} \quad r = a, b. \quad (28)
\]

Substitution from (26) and (27) into (25) yields

\[
\frac{\partial}{\partial r} (C_{66} u_{rz} + e_{26} \phi_r) + \frac{1}{r} (C_{66} u_{rz} + e_{26} \phi_r) = -\rho \omega^2 u_z, \quad (29)
\]

J. S. Yang and R. C. Batra: Vibrations of piezoelectric shell
FIG. 3. A circular cylindrical shell and the choice of base vectors for studying its tangential thickness shear vibrations.

\[
\frac{\partial}{\partial r} \left( e_{26} u_{z,r} - e_{22} \phi_r \right) + \frac{1}{r} \left( e_{26} u_{z,r} - e_{22} \phi_r \right) = 0. \tag{30}
\]

The elimination of \( \phi \) from (29) and (30) gives

\[
u_{z,r} + \frac{1}{r} u_{z,r} + k^2 u_z = 0, \tag{31}
\]

where

\[
k^2 = \frac{\rho \omega^2}{C_{66}} \quad \dot{C}_{66} = C_{66} + e_{26}^2/e_{22}. \tag{32}
\]

Solving Eqs. (31) and (30) for \( u_z \) and \( \phi \), we obtain

\[
u_{z} = C_1 J_0(kr) + C_2 Y_0(kr), \tag{33}
\]

\[
\phi = \frac{e_{26}}{e_{22}} u_z + \frac{e_{26}}{e_{22}} (C_3 \ln r + C_4), \tag{34}
\]

where \( J_0 \) and \( Y_0 \) are zeroth-order Bessel’s functions of the first and second kind, respectively, and constants \( C_1, C_2, C_3, \) and \( C_4 \) are to be determined from the boundary conditions. The requirement that functions \( u_z \) and \( \phi \) satisfy boundary conditions (28) give four homogeneous equations for the determination of \( C_1, C_2, C_3, \) and \( C_4 \). These four equations have a nontrivial solution only if

\[
kaJ_1(ka)\ln a/b + k_{26}^2[J_0(ka) - J_0(kb)]
\]

\[
kbJ_1(kb) \ln a/b + k_{26}^2[J_0(ka) - J_0(kb)]
\]

\[
= \frac{ka Y_1(ka) \ln a/b + k_{26}^2[Y_0(ka) - Y_0(kb)]}{kb Y_1(kb) \ln a/b + k_{26}^2[Y_0(ka) - Y_0(kb)]}. \tag{35}
\]

where relations \( J_0' = -J_1, Y_0' = -Y_1 \) have been used; \( J_1 \) and \( Y_1 \) are first-order Bessel’s functions of the first and second kind, respectively. Equation (35) is the equation for the determination of the frequency \( k \), and thence \( \omega \) through Eq. (32).

III. TANGENTIAL THICKNESS SHEAR VIBRATIONS OF A CIRCULAR CYLINDRICAL SHELL

We now study the tangential thickness shear vibrations of a cylindrical shell made of a monoclinic crystal aligned as shown in Fig. 3 wherein the coordinate system is also depicted. With respect to the coordinate axes shown, the constitutive relations take the form

\[
T_{\theta\theta} = C_{11} S_{\theta\theta} + C_{12} S_{rr} + C_{13} S_{z\theta} + 2C_{14} S_{rz} - e_{11} E_\theta ,
\]

\[
T_{rr} = C_{12} S_{\theta\theta} + C_{22} S_{rr} + C_{23} S_{z\theta} + 2C_{24} S_{rz} - e_{12} E_\theta ,
\]

\[
T_{z\theta} = C_{33} S_{\theta\theta} + C_{31} S_{rr} + C_{32} S_{z\theta} + 2C_{34} S_{rz} - e_{13} E_\theta ,
\]

\[
T_{r\theta} = C_{13} S_{\theta\theta} + C_{23} S_{rr} + C_{33} S_{z\theta} + 2C_{44} S_{rz} - e_{13} E_\theta ,
\]

\[
T_{\theta r} = 2C_{56} S_{\theta z} + 2C_{66} S_{rr} - e_{26} E_\theta - e_{36} E_z ,
\]

\[
D_\theta = e_{11} S_{\theta\theta} + e_{12} S_{rr} + e_{13} S_{z\theta} + 2e_{14} S_{rz} + e_{11} E_\theta ,
\]

\[
D_r = 2e_{26} S_{\theta\theta} + 2e_{56} S_{rr} + e_{22} E_r + e_{23} E_z ,
\]

\[
D_{z\theta} = 2e_{36} S_{\theta z} + 2e_{36} S_{rr} + e_{33} E_r + e_{33} E_z .
\]

We assume that the free-time-harmonic thickness shear vibrations in the tangential direction are given by

\[
u_{\theta} = \bar{u}_\theta(r)e^{i\omega t}, \quad u_r = 0, \quad u_z = 0, \quad \phi = \bar{\phi}(r)e^{i\omega t}. \tag{37}
\]

For motions of this type, the governing equations and boundary conditions simplify to

\[
\frac{\partial T_{rr}}{\partial r} + \frac{2}{r} T_{r\theta} = -\rho \omega^2 u_\theta , \quad \frac{1}{r} \frac{\partial}{\partial r} (r D_r) = 0, \tag{38}
\]

\[
S_{r\theta} = \frac{1}{2} \left( u_{\theta,r} - \frac{u_\theta}{r} \right) , \quad E_r = -\phi_r , \tag{39}
\]

\[
T_{z\theta} = 2e_{26} S_{\theta z} + 2e_{56} S_{rr} - e_{26} E_r , \quad T_{r\theta} = 2e_{56} S_{r\theta} - e_{26} E_z , \tag{40}
\]

\[
D_{r\theta} = 2e_{26} S_{\theta\theta} + e_{22} E_r , \quad D_{z\theta} = 2e_{36} S_{\theta z} + e_{33} E_z , \tag{41}
\]

\[
T_{r\theta} = 0, \quad \phi = 0 \quad \text{at} \quad r = a, b , \tag{42}
\]

where we have dropped the tilde superimposed upon \( u_\theta \) and \( \phi \). A solution of Eq. (38) is

\[
D_r = e_{26} C_3/r , \tag{43}
\]

where \( C_3 \) is an arbitrary constant. Equations (43), (41), and (39) result in

\[
\phi_r = \frac{e_{26}}{e_{22}} \left( 2S_{r\theta} - \frac{C_3}{r} \right). \tag{44}
\]

Substitution from (40), (39), and (44) into (38) yields

\[
u_{\theta,r} + \frac{1}{r} u_{\theta,r} + \left( \frac{k^2}{r^2} - \frac{1}{r^2} \right) u_\theta = -\frac{k_{26}^2 C_3}{r^2} , \tag{45}
\]

where \( k \) and \( k_{26} \) are defined by Eqs. (32) and (22), respectively. A solution of Eq. (45) is

\[
u_{\theta} = C_1 J_1(kr) + C_2 Y_1(kr) + C_3 P(kr) , \tag{46}
\]

where \( C_1 \) and \( C_2 \) are arbitrary constants, and

\[
P(kr) = \frac{\pi}{2} e_{26} \int_{ka}^{kr} \frac{Y_1(\xi)}{\xi} d\xi , \quad G(kr) = \int_{ka}^{kr} \frac{Y_1(\xi)}{\xi} d\xi. \tag{47}
\]

Substituting from (39) and (46) into (44), and integrating the resulting equation, we obtain

\[
\phi = \left[ C_1 (J_1(kr) - F(kr)) + C_2 (Y_1(kr) - G(kr)) \right] + C_3 (P(kr) - Q(kr) - \ln r) + C_4 , \tag{48}
\]

J. S. Yang and R. C. Batra: Vibrations of piezoelectric shell
FIG. 4. First four resonant frequencies for axial thickness shear vibrations of a circular cylindrical shell (— 1st; —— 2nd; ——— 3rd; ——– 4th).

where

\[ Q(kr) = \int_{ka}^{kr} \frac{P(\xi)}{\xi^2} d\xi. \]  (50)

\[
\begin{align*}
\frac{[P(kb) - Q(kb) + \ln a/b]kaJ_3(ka) + [J_1(ka) - J_1(kb) + F(kb)]k_2^2}{[P(kb) - Q(kb) + \ln a/b]kbJ_2(kb) + [J_1(ka) - J_1(kb) + F(kb)][P(kb) - kbP'(kb) + k_2^2]} \\
\frac{[P(kb) - Q(kb) + \ln a/b]kaY_2(ka) + [Y_1(ka) - Y_1(kb) + G(kb)]k_2^2}{[P(kb) - Q(kb) + \ln a/b]kbY_2(kb) + [Y_1(ka) - Y_1(kb) + G(kb)][P(kb) - kbP'(kb) + k_2^2]},
\end{align*}
\]  (51)

which is the desired equation for the determination of \( k \) and \( \omega \) via Eq. (17).

IV. NUMERICAL RESULTS

For a rotated Y-cut quartz, \( C_{66} = 29.01 \) GPa,

\[ e_{26} = -0.095 \text{ C/m}^2, \]

\[ e_{22} = 39.82 \times 10^{-12} \text{ C/V m}, \]

frequency equations (35) and (51) are solved numerically, and the first four frequencies are depicted in Figs. 4 and 5, respectively. In Figs. 4 and 5, \( R = (a + b)/2 \) is the average radius of the cylinder. Keeping \( 2h = b - a \) fixed and letting \( a \to \infty \), we see that in each case the resonant frequencies of the cylindrical shell approach those of the flat plate given by (22).

V. CONCLUSIONS

We have studied analytically the axial and the tangential thickness shear vibrations of a circular cylindrical piezoelectric shell, and have computed the first four resonant frequencies for a rotated Y-cut quartz shell.
